### ABSTRACT

Cesarean scar ectopic pregnancy (CSEP) is a rare but potentially life-threatening form of ectopic pregnancy. We report a case of a 30-year-old G4P3 woman who presented at 12 weeks + 5 days of gestation with lower abdominal pain and severe vaginal bleeding. She had a history of three prior cesarean deliveries. Clinical evaluation and intraoperative findings confirmed a ruptured cesarean scar pregnancy. CSEP can remain undiagnosed until rupture occurs. High clinical suspicion, early imaging, and timely intervention are essential to reduce both maternal morbidity and mortality.
